Overview

What is a Network made of?

How is it shared?

How is it organized?

How does communication happen?

How do we characterize it?

Networks are composed of three basic components

End-systems send & receive data

End-systems come in a wide-variety

Switches & routers forward data to the destination

Routers/switches vary in size and usage

Home
router

~20 cm

0,5 kg

1 Gbps

Internet core
router

>200cm

700kg

>12 Tbps

(>920 Tbps in
multi-chassis*)

*https://www.cisco.com/c/en/us/products/collateral/routers/carrier-routing-system/data_sheet_c78-726136.html

Links connect end-systems to switches
and switches to each other

Links, too, vary in size and usage

Copper

ADSL, RJ-45,...

Optical fibers

Wireless link

The *Inter*net is a network of networks

Internet Service Providers

There exists a huge amount of **access technologies**

Ethernet	most common, symmetric
DSL	over phone lines, asymmetric
CATV	via cable TV, shared
Cellular	smart phones
Satellite	remote areas
FTTH	household
Fibers	Internet backbone
Infiniband	High performance computing

Compare these three designs in terms of
sharing, **resiliency**, and **per-node capacity**

design

full-mesh

chain

bus

advantages

disadvantages

Switched networks provide **reasonable** and **flexible** compromise

design

switched

advantages

sharing and per-node capacity can be adapted
to fit the network needs

disadvantages

require smart devices to perform:
forwarding, routing, **resource allocation**

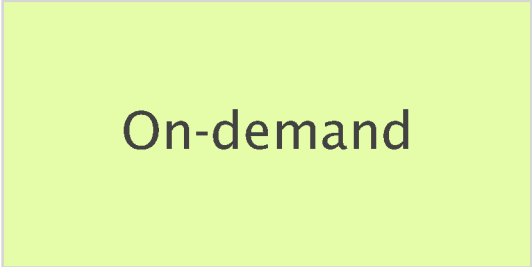

Links and switches are shared between flows

There exist two approaches to sharing:
reservation and **on-demand**

Reservation

On-demand

principle

reserve the bandwidth
you need in advance

send data when you need

Both are examples of **statistical multiplexing**

Reservation

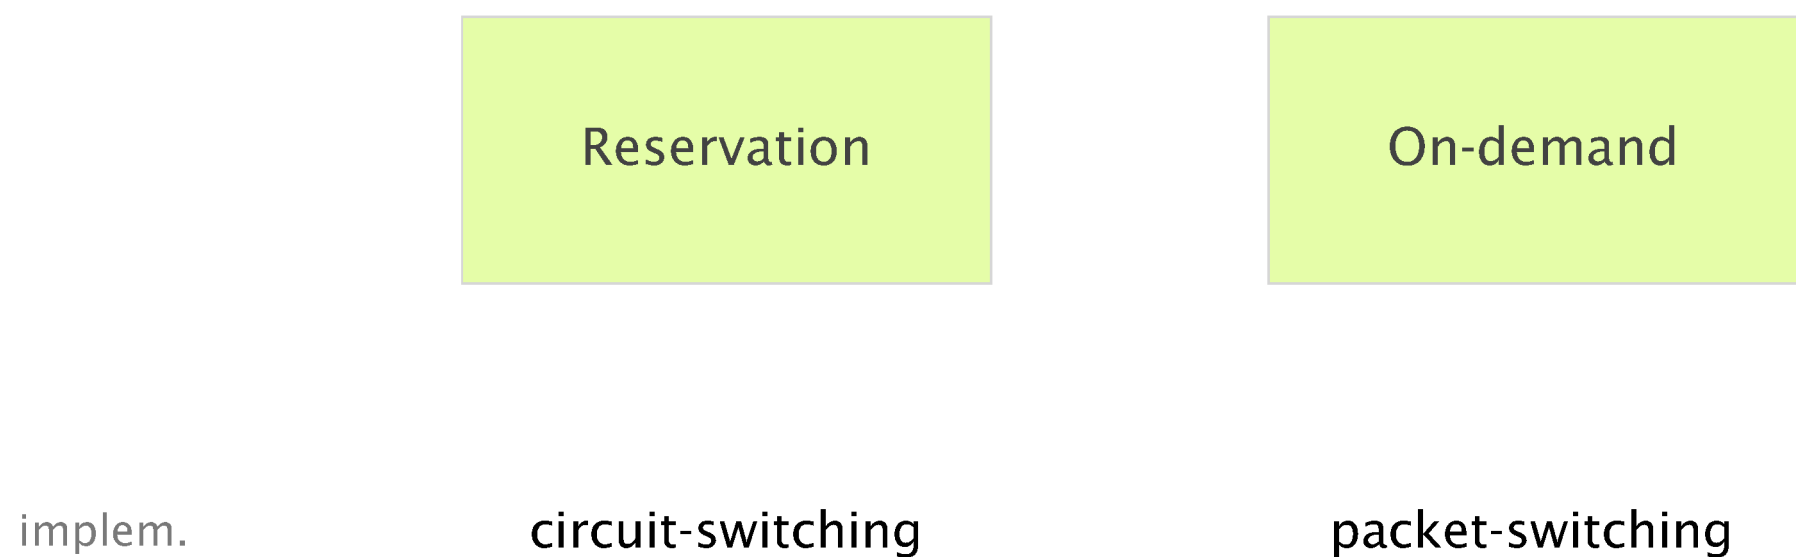

On-demand

multiplexing

at the flow-level

at the packet-level

The two approaches are implemented using circuit-switching or packet-switching, respectively

Reservation

The diagram consists of two light green rectangular boxes with thin black borders. The left box contains the word 'Reservation' and is positioned above the text 'circuit-switching'. The right box contains the words 'On-demand' and is positioned above the text 'packet-switching'. To the left of these boxes, the text 'implem.' is aligned with the vertical center of the boxes.

On-demand

implem.

circuit-switching

packet-switching

Reservation

On-demand

implem.

circuit-switching

packet-switching

Circuit switching relies on the Resource Reservation Protocol

- (1) **src** sends a reservation request for 10Mbps to **dst**
- (2) switches “establish a circuit”
- (3) **src** starts sending data
- (4) **src** sends a “teardown circuit” message

Let's walk through example of data transfer using circuit switching

The efficiency of the transfer depends on how utilized the circuit is once established

This is an example of poor efficiency.

The circuit is mostly idle due to traffic bursts

This is another example of poor efficiency.
The circuit is used for a short amount of time

Another problem of circuit switching is that it doesn't route around trouble

A is forced to signal a new circuit to restore communication

Pros and cons of circuit switching

advantages

predictable performance

simple & fast switching
once circuit established

disadvantages

inefficient if traffic is bursty or short

complex circuit setup/teardown
which adds delays to transfer

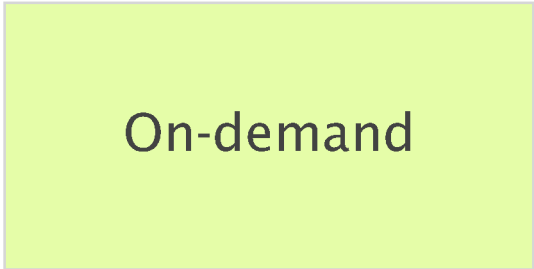

requires new circuit upon failure

What about packet switching?

Reservation

circuit-switching

On-demand

packet-switching

In packet switching,
data transfer is done using independent packets

Each packet contains a destination (**dst**)

Since packets are sent without global coordination, they can “clash” with each other

To absorb transient overload,
packet switching relies on buffers

To absorb transient overload,
packet switching relies on buffers

Packet switching routes around trouble

route recomputed
on the fly by s2

Pros and cons of packet switching

advantages

efficient use of resources

simpler to implement

route around trouble

disadvantages

unpredictable performance

requires buffer management and
congestion control

Packet switching beats circuit switching
with respect to *resiliency* and *efficiency*

Internet  packets

Packet switching will be our focus for the rest of the course

So far, this is our vision of the Internet...

The real Internet is a “tad” more complex
